Avidin Biotin Blocking Reagent 901-AB972-031523

Available Product Formats		
Catalog Number	Volume	
AB972H	25 mL	
AB972L	100 mL	
AB972M	500 mL	

Intended Use:

For in vitro Diagnostic Use

The Avidin-Biotin Kit is intended for laboratory professional use to reduce incidence of background staining due to endogenous avidin and biotin in either manual or automated immunohistochemistry (IHC) staining protocols on formalin-fixed, paraffin-embedded (FFPE) tissues. The clinical interpretation of any staining or its absence should be complemented by morphological studies and proper controls and should be evaluated within the context of the patient's clinical history and other diagnostic tests by a qualified pathologist.

Summary and Explanation:

Avidin-Biotin Kit is used to reduce background staining caused by the presence of endogenous avidin and biotin that is often observed with immunohistochemistry. The Avidin and Biotin solutions are color-coded with a pH indicator. In most cases, endogenous biotin in tissue sections is masked by formalin fixation. However, if avidin-biotin IHC detection systems are used with frozen sections or tissues pretreated with a heat-induced, epitope retrieval method (HIER), an avidin-biotin blocking technique may be needed. It can also be used on an automated staining system.

Principle of Procedure:

This blocking reagent, when applied to pretreated formalin-fixed, paraffinembedded tissue sections either prior to application of the primary antibody or after the application of primary antibody, reduces background staining that may be observed in IHC.

Materials and Methods:

Reagents Provided:

Kit Catalog No.	Component Catalog No.	Component Description	Quantity x Volume
AB972H	AB972H-A	Avidin	1 x 25 mL
	AB972H-B	Biotin	1 x 25 mL
AB972L	AB972H-A	Avidin	4 x 25 mL
	AB972H-B	Biotin	4 x 25 mL
AB972M	AB972M-A	Avidin	1 x 500 mL
	AB972M-B	Biotin	1 x 500 mL

Reconstitution, Mixing, Dilution, Titration:

The Avidin-Biotin Kit is optimized for use with Biocare antibodies and ancillary reagents and ready to use with Biocare IHC antibodies and ancillary reagents. No reconstitution, mixing, dilution, or titration is required.

Known Applications:

Immunohistochemistry (formalin-fixed paraffin-embedded tissues)

Supplied As:

Avidin - AB972-A

Buffered saline solution, contains avidin, pH 8.6-8.7, and 0.15% ProClin 950 preservative. See Safety Data Sheet for additional details.

Buffered saline solution, contains biotin, pH 8.6 – 8.7, and 0.15% ProClin 950 preservative. See Safety Data Sheet for additional details.

Materials and Reagents Needed but Not Provided:

Microscope slides, positively charged

Positive and negative tissue controls

Desert Chamber* or similar Drying oven (optional)

Xylene or xylene substitute

Ethanol or reagent alcohol

Decloaking Chamber* or similar pressure cooker (optional)

Deionized or distilled water

Wash buffer*

Pretreatment reagents* (optional)

Enzyme digestion* (optional)

Peroxidase block* (optional)

Protein block* (optional)

Primary antibody*

Negative control reagents*

Detection kits*

Chromogens*

Hematoxylin* (counterstain)

Bluing reagent*

Mounting medium*

Coverglass

Light Microscope (40-400X magnification)

* Biocare Medical Products: Refer to the Biocare Medical website located at http://biocare.net for information regarding catalog numbers and ordering. Certain reagents listed above are based on specific application and detection system used.

Storage and Stability:

Store at 2°C to 8°C. The product is stable to the expiration date printed on the vial label when stored under these conditions. Do not use after expiration date. Storage under any condition other than those specified must be verified. The kit reagent(s) are ready-to-use and should not be diluted. The stability of user diluted reagent has not been established by Biocare.

Specimen Preparation:

Tissues fixed in formalin are suitable for use prior to paraffin embedding. Osseous tissues should be decalcified prior to tissue processing to facilitate tissue cutting and prevent damage to microtome blades. 1,2

Properly fixed and embedded tissues expressing the specified antigen target should be stored in a cool place. The Clinical Laboratory Improvement Act (CLIA) of 1988 requires in 42 CFR §493.1259(b) that "The laboratory must retain stained slides at least ten years from the date of examination and retain specimen blocks at least two years from the date of examination."3

Treatment of Tissues Prior to Staining:

Perform Heat Induced Epitope Retrieval (HIER) per recommended protocol below. The routine use of HIER prior to IHC has been shown to minimize inconsistency and standardize staining.4,5

Warning and Precautions:

- 1. Kit reagents contain less than 0.05% ProClin 300 and/or less than 1% ProClin 950. Wear gloves and protective clothing and take reasonable precautions when handling as ProClin is classified as an irritant and may cause skin contact sensitization. Avoid contact with eyes, skin, and mucous membranes
- 2. Handle materials of human or animal origin as potentially biohazardous and dispose such materials with proper precautions. In the event of exposure, follow the health directives of the responsible authorities where used.6,7
- 3. Specimens, before and after fixation, and all materials exposed to them should be handled as if capable of transmitting infection and disposed of with proper precautions. Never pipette reagents by mouth and avoid contacting the skin and mucous membranes with reagents and specimens. If reagents or specimens come into contact with sensitive areas, wash with copious amounts of water.8

Avidin Biotin Blocking Reagent 901-AB972-031523

BIOCARE

- 4. Microbial contamination of reagents may result in an increase in nonspecific staining.
- 5. Incubation times or temperatures other than those specified may give erroneous results. The user must validate any such change.
- 6. Do not use reagent after the expiration date printed on the vial.
- 7. The micro-polymer detection kit reagent(s) are optimized and ready to use with Biocare antibodies and ancillary reagents. Refer to the primary antibody and other ancillary reagent instructions for use for recommended protocols and conditions for use.
- 8. Follow local and/or state authority requirements for method of disposal.
- 9. The SDS is available upon request and is located at http://biocare.net.
- 10. Report any serious incidents related to this device by contacting the local Biocare representative and the applicable competent authority of the Member State or country where the user is located.

Instructions for Use:

The Avidin-Biotin Kit reagents are optimized for use with Biocare antibodies and ancillary reagents. Refer to the primary antibody information for use for recommended protocols and conditions for use. Incubation times and temperatures will vary depending on the specific antibody protocol followed.

When using an automated staining instrument, consult the specific instrument operator manual and instructions for use for operating parameters.

- 1. After incubation with normal serum, incubate section or cells with Avidin Solution for 10-20 minutes.
- 2. Rinse with wash buffer.
- 3. Incubate tissue or cells for 10-20 minutes with the Biotin Solution.
- 4. Rinse in 3 changes of wash buffer.

These steps can be performed either prior to application of the primary antibody or can be performed after the application of primary antibody. In some cases, the application of these solutions prior to or after the primary antibody can block specific staining. For strong endogenous biotin staining, longer incubation times with the avidin-biotin solutions may be required. Some tissues, such as kidney, liver, lung, spleen, breast and brain may contain endogenous biotin. To detect endogenous biotin staining, cut two additional slides from the same block and test with the following procedure: Slide 1:

- A) Pretreat tissue or cells in the normal way and omit the primary and secondary antibody.
- B) Apply a streptavidin-conjugate and a substrate to the tissue or cells. Slide 2:
- A) Pretreat the tissue or cells identically to slide 1.
- B) Apply only the substrate to the tissue.

Lightly counterstain with hematoxylin (5 seconds), dehydrate, clear and coverslip. Observe slides under a microscope. If there is no background staining in slide 2, then the background staining in slide 1 is most likely due to endogenous biotin.

Technical Note: The blocking kit consists of equal amounts of an Avidin solution (pale pink) and of a Biotin solution (pale blue). Pretreatment of tissues with the Avidin solution should always be followed by incubation with the Biotin solution. If the Avidin solution turns from a pale pink to orange or yellow, the pH of the solution has changed, and it should not be used. If the Biotin solution turns from a pale blue to green or yellow, the pH of the solution has changed and should not be used. The correct color of these solutions will assure the end-user that proper pH and optimum performance is being maintained.

Quality Control:

Refer to CLSI Quality Standards for Design and Implementation of Immunohistochemistry Assays; Approved Guideline-Second edition (I/LA28-A2) CLSI Wayne, PA USA (www.clsi.org). 20119

Positive and negative controls should be run simultaneously with all patient specimens. If unexpected staining is observed which cannot be explained by variations in laboratory procedures and a problem with the reagent is suspected, contact Biocare's Technical Support at 1-800-542-2002 or via the technical support information provided on biocare.net.

Positive Tissue Control:

External positive control materials should be fresh specimens fixed, processed, and embedded as soon as possible in the same manner as the patient sample(s). Positive tissue controls are indicative of correctly prepared tissues and proper staining techniques. One positive external tissue control for each set of test conditions should be included in each staining run.

The tissues used for the external positive control materials should be selected from patient specimens with well-characterized low levels of the positive target activity that gives weak positive staining. The low level of positivity for external positive controls is designed so to ensure detection of subtle changes in the primary antibody sensitivity from instability or problems with the IHC methodology. Commercially available tissue control slides or specimens processed differently from the patient sample(s) validate reagent performance only and do not verify tissue preparation.

Known positive tissue controls should only be utilized for monitoring the correct performance of processed tissues and test reagents, rather than as an aid in formulating a specific diagnosis of patient samples. If the positive tissue controls fail to demonstrate positive staining, results with the test specimens should be considered invalid.

Negative Tissue Control:

Use a negative tissue control fixed, processed, and embedded in a manner identical to the patient sample(s) with each staining run to verify the specificity of the IHC primary antibody for demonstration of the target antigen, and to provide an indication of specific background staining (false positive staining). Also, the variety of different cell types present in most tissue sections can be used by the laboratorian as internal negative control sites to verify the IHC's performance specifications. The types and sources of specimens that may be used for negative tissue controls are listed in the Performance Characteristics section.

If specific staining (false positive staining) occurs in the negative tissue control, results with the patient specimens should be considered invalid.

Nonspecific Negative Reagent Control:

Use a nonspecific negative reagent control in place of the primary antibody with a section of each patient specimen to evaluate nonspecific staining and allow better interpretation of specific staining at the antigen site. Ideally, a negative reagent control contains an antibody produced and prepared (i.e., diluted to same concentration using same diluent) for use in the same way as the primary antibody but exhibits no specific reactivity with human tissues in the same matrix/solution as the Biocare antibody. Diluent alone may be used as a less desirable alternative to the previously described negative reagent controls. The incubation period for the negative reagent control should correspond to that of the primary antibody.

When panels of several antibodies are used on serial sections, the negatively staining areas of one slide may serve as a negative/nonspecific binding background control for other antibodies. To differentiate endogenous enzyme activity or nonspecific binding of enzymes from specific immunoreactivity, additional patient tissues may be stained exclusively with substrate-chromogen or enzyme complexes (PAP, avidin-biotin, streptavidin) and substrate-chromogen, respectively.

Assay Verification:

Prior to initial use of an antibody or staining system in a diagnostic procedure, the user should verify the antibody's specificity by testing it on a series of inhouse tissues with known immunohistochemical performance characteristics representing known positive and negative tissues. Refer to the quality control

Pacheco, CA 94553

EC REP EMERGO EUROPE

Avidin Biotin Blocking Reagent 901-AB972-031523

procedures previously outlined in this section of the product insert and to the quality control recommendations of the CAP Certification Program¹⁰ for Immunohistochemistry and/or the NCCLS IHC guideline¹¹. These quality control procedures should be repeated for each new antibody lot, or whenever there is a change in assay parameters. Tissues listed in the Performance Characteristics section are suitable for assay verification.

Troubleshooting:

Follow the antibody specific protocol recommendations according to data sheet provided. If atypical results occur, contact Biocare's Technical Support at 1-800-542-2002.

Interpretation of Staining:

A primary antibody works in conjunction with ancillary reagents to produce a colored reaction at the antigen sites localized by the primary antibody. Background block ancillary reagents assist with reducing non-specific background staining to facilitate interpretation of the antibody-antigen specific staining reaction. Prior to interpretation of patient results, the staining of controls must be evaluated by a qualified pathologist. Negative controls are evaluated and compared to stained slides to ensure any staining observed is not a result of nonspecific interactions.

Positive Tissue Control:

The positive tissue control stained with indicated antibody should be examined first to ascertain that all reagents are functioning properly. The appropriate staining of target cells (as indicated above) is indicative of positive reactivity. If the positive tissue controls fail to demonstrate positive staining, any results with the test specimens should be considered invalid.

The color of the reaction product may vary depending on substrate chromogens used. Refer to substrate package inserts for expected color reactions. Further, metachromasia may be observed in variations of the method of staining.13

When a counterstain is used, depending on the incubation length and potency of the counterstain used, counterstaining will result in a coloration of the cell nuclei. Excessive or incomplete counterstaining may compromise proper interpretation of results. Refer to protocol(s) for recommended counterstain.

Negative Tissue Control:

The negative tissue control should be examined after the positive tissue control to verify the specificity of the labeling of the target antigen by the primary antibody. The absence of specific staining in the negative tissue control confirms the lack of antibody cross reactivity to cells/cellular components. If specific staining (false positive staining) occurs in the negative external tissue control, results with the patient specimen should be considered invalid.

Nonspecific staining, if present, usually has a diffuse appearance. Sporadic staining of connective tissue may also be observed in sections from excessively formalin-fixed tissues. Use intact cells for interpretation of staining results. Necrotic or degenerated cells often stain nonspecifically.

Examine patient specimens stained with indicated antibody last. Positive staining intensity should be assessed within the context of any nonspecific background staining of the negative reagent control. As with any immunohistochemical test, a negative result means that the antigen was not detected, not that the antigen was absent in the cells/tissue assayed. If necessary, use a panel of antibodies to identify false-negative reactions. Refer to Summary and Explanation, Limitations, and Performance Characteristics for specific information regarding indicated antibody immunoreactivity.

Limitations:

General Limitations:

- 1. For *in vitro* diagnostic (IVD) Use
- 2. This product is for professional use only: Immunohistochemistry is a multistep diagnostic process that consists of specialized training in the selection of the appropriate reagents; tissue selection, fixation, and processing; preparation of the IHC slide; and interpretation of the staining results.
- For use by physician prescription only. (Rx Only)
- 4. Tissue staining is dependent on the handling and processing of the tissue prior to staining. Improper fixation, freezing, thawing, washing, drying, heating, sectioning or contamination with other tissues or fluids may produce artifacts, antibody trapping, or false negative results. Inconsistent results may be due to variations in fixation and embedding methods, or to inherent irregularities within the tissue. 12
- Excessive or incomplete counterstaining may compromise proper interpretation of results.
- The clinical interpretation of any positive or negative staining should be evaluated within the context of clinical presentation, morphology, and other histopathological criteria. The clinical interpretation of any positive or negative staining should be complemented by morphological studies using proper positive and negative internal and external controls as well as other diagnostic tests. It is the responsibility of a qualified pathologist who is familiar with the proper use of IHC antibodies, reagents, and methods to interpret all the steps used to prepare and interpret the final IHC preparation.
- 7. The optimum protocols for a specific application can vary. These include, but are not limited to fixation, heat-retrieval method, incubation times, antibody dilution, tissue section thickness and detection kit used. Refer to the primary antibody and other ancillary reagent instructions for use for recommended protocols and conditions for use. The data sheet recommendations and protocols are based on exclusive use of Biocare products. Ultimately, it is the responsibility of the investigator to determine optimal conditions.
- This product is not intended for use in flow cytometry. Performance characteristics have not been determined for flow cytometry.
- Tissues from persons infected with hepatitis B virus and containing hepatitis B surface antigen (HBsAg) may exhibit nonspecific staining with horseradish peroxidase.14
- 10. Reagents may demonstrate unexpected reactions in previously untested tissues. The possibility of unexpected reactions even in tested tissue groups cannot be completely eliminated due to biological variability of antigen expression in neoplasms, or other pathological tissues. 15 Contact Biocare's Technical Support at 1-800-542-2002, or via the technical support information provided on biocare.net, with documented unexpected reaction(s).
- 11. Normal/nonimmune sera from the same animal source as secondary antisera used in blocking steps may cause false-negative or false-positive results due to autoantibodies or natural antibodies.
- 12. False-positive results may be seen due to non-immunological binding of proteins or substrate reaction products. They may also be caused by pseudo peroxidase activity (erythrocytes), endogenous peroxidase activity (cytochrome C), or endogenous biotin (e.g., liver, breast, brain, kidney) depending on the type of immunostain used. 13
- 13. A negative result means that the antigen was not detected, not that the antigen was absent in the cells or tissue examined.

Product Specific Limitations:

No product specific limitations.

Performance Characteristics:

Staining was performed using protocols provided in the antibody specific instructions for use or as specified. Sensitivity and specificity of staining was evaluated across a range of normal and neoplastic tissue types evaluated during development of primary antibodies.

EC REP EMERGO EUROPE

Avidin Biotin Blocking Reagent 901-AB972-031523

Reproducibility:

The reproducibility of Biocare's blocking reagents is verified through a measurement of intermediate precision in which various reagent lots were tested over an extended period of time using various operators, analysts, reagent lots, tissue samples, and equipment. The staining obtained for each detection reagent evaluated was consistent and performed as expected.

Troubleshooting:

- No staining of any slides Check to determine appropriate positive control tissue, antibody, and detection products have been used. Check for incomplete or improper wax removal or pretreatment.
- Weak staining of all slides Check to determine appropriate positive control tissue, antibody, and detection products have been used.
- Excessive background of all slides There may be high levels of endogenous biotin (if using biotin-based detection products), endogenous HRP activity converting chromogen to colored end product (use peroxidase block), or excess non-specific protein interaction (use a protein block, such as serum- or casein-based blocking solution).
- Tissue sections wash off slides during incubation Check slides to ensure they are positively charged.
- Specific staining too dark Check protocol to determine if proper antibody titer was applied to slide, as well as proper incubation times for all reagents. Additionally, ensure the protocol has enough washing steps to remove excess reagents after incubation steps are completed.
